Getting Started

First of all, get **nowic/psets/pset02** from **github** and you may see the following files:

- **pset02sorting.pdf** – this file
- **random.pdf** – reading material about random number generation.
- **quicksort.cpp, bubble.cpp, insertion.cpp, selection.cpp** – provided previously..
- **sortDriver1.cpp** – Skeleton code that runs various sorting algorithms interactively. Watch out the usage of **clock()** that measures the elapse time of the processor.
- **sortx.exe, sortx** – A solution provided to compare it with your work.
- **include/nowic.h** – contains user-defined function prototypes such as **GetInt()**, **GetChar()** and **GetString()**.
- **lib/libnowic.a** - an user-defined static library to link with. It is for Windows.
lib/libnowic_mac.a – It is for MacOS.

Step 1: Build a static library – libsort.a

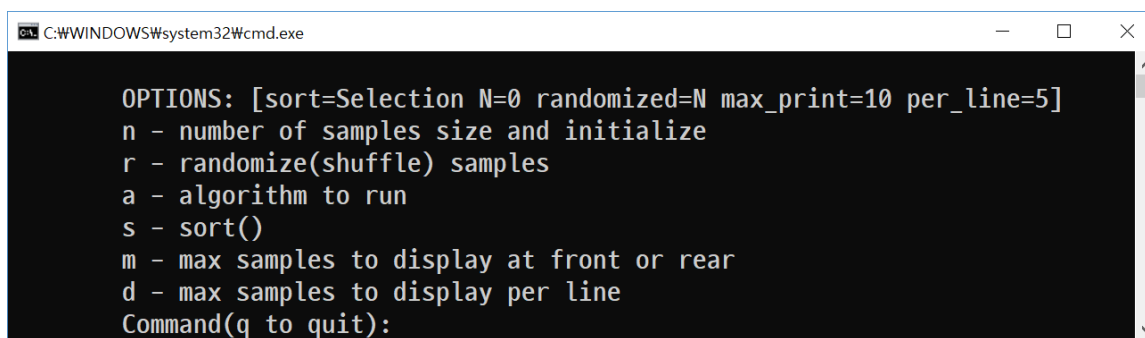

Since you studied about the static library and build process. Let's build a static library with four sorting files provided before. Even though it is simpler to use a command to build it, you should also create a makefile (name it **make.s**) to practice the usage of make and makefile. Once you make it and you must place **libsort.a** in **nowic/lib** folder in your system.

As a part of pset, you must submit **libsort.a** and its makefile called **make.s**.

Step 2: Handling an arbitrary number of samples

We would like to rewrite the sort program we have been using. While you follow the instructions step by step, you will eventually complete the specifications of this pset

Firstly, we want to sort an arbitrary number of samples and display its result. You follow the skeleton code, **sortDriver1.cpp**, and implement the code that works like **sortx.exe** provided as a guideline.

```
C:\WINDOWS\system32\cmd.exe

OPTIONS: [sort=Selection N=0 randomized=N max_print=10 per_line=5]
n - number of samples size and initialize
r - randomize(shuffle) samples
a - algorithm to run
s - sort()
m - max samples to display at front or rear
d - max samples to display per line
Command(q to quit):
```

This code shows some sorting options such that the user can set them up interactively. For example, the number of samples to sort can be set freely and select one of sorting algorithms available. Also, the input and output data can be display as user's specification. It is useful when you can check the sorting of the large data set. I recommend that you fully understand those options given, especially, **options m and d**.

Many options in the following menu are self-explanatory. The first line which begins with "**OPTIONS**" the menu shows the current status of user's choices. The skeleton code in **sortDriver1.cpp** also offers you to follow when you code.

Option n

Get an integer input from the user. If the user enters wrong, keep on asking "Retry". If user's input is less than 1, display an error message and go to the menu. If user's input is valid, do the following.

1. set N, the number of samples, with the new value that the user entered.
2. Before allocating the new list, free the old list if not nullptr
3. Allocate memory for new data samples
4. Fill the list with numbers from 0 to N - 1.
5. Print the new list and go the menu.

Note: Don't use **malloc()** and **free()**, but use **new** and **delete** since we are learning C++ from now on.

Option a

Provide the sorting algorithms such as Bubble, Insertion, Quicksort, and Selection sort. The use may select one of the **algorithms**.

You may follow suggestions described in the code. It may be a good chance to use an enumerated data type. Here is an example which is a self-explanatory.

```
// definition of Color type
enum Color {RED, GREEN, BLUE, WHITE, PURPLE, ... };

// variable declarations
enum Color x, y, z;

x = BLUE;
y = WHITE;
z = PURPLE;
if (x == BLUE){
    ...
}

switch(y){
    case WHITE:
        ...
}
```

Instead of Color, we may name our algorithms as shown below:

```
enum algorithm_list {BUBBLE, INSERTION, QUICKSORT, SELECTION};
enum algorithm_chosen;    // set it menu item a
                          // used in menu item s with a switch statement
```

Option r

If the list is newly created or sorted, the list is filled with sorted numbers. Therefore, it is common that the list elements are shuffled before sorting. Do this coding with the following function proto-type.

```
void randomize(int list[], int n);
```

For every sample, starting from the first element in the list, it is swapped with the element randomly selected by the index generated by a 'real' (not pseudo) random number out of from 0 to N-1.

Hint: Refer to **rand()** and **srand()** functions explained random.pdf.

Tips and Hints:

We need to generate n distinct random numbers from 0 to n – 1 and store them in an array. For this problem, you may refer to an algorithm [here](#). It is so-called method. Here is a simple way to do it.

For example, let us suppose that we have an int array `a[]` and `n = 100`.

Set `a[0] = 0`, `a[1] = 1`, ... , `a[99] = 99`.

For loop from `i = 0` to `99`:

Get a random number `r`.

Swap two values: `a[i]` and `a[r]`

Option s

This option executes the algorithm which is already set previously. According to the options the user sets, execute sorting itself and display its result.

Option m and Option d

In these options, you write the following function.

```
void printList(int *list, int n, int max_print, int per_line);
```

When we have a **very long list**, we want to print some in the front part of the list and some in the rear part of the list. The **max_print** specifies the number of samples in either front or rear part of the list. The **per_line** determines how many samples prints per line. If **max_print** is larger than or equal to the sample size **N**, **max_print** becomes **N/2** samples only.

By default, **max_print (set by option m)** and **per_line (set by option d)** are 10 and 5, respectively.

For example:

Case 1) `N = 12`, `max_print = 100`, `per_line = 20`

```
0    1    2    3    4    5
6    7    8    9   10   11
```

Case 2) `N = 12`, `max_print = 100`, `per_line = 4`

```
0    1    2    3
4    5
6    7    8    9
10   11
```

Case 3) `N = 12`, `max_print = 4`, `per_line = 6`

```
0    1    2    3
8    9   10   11
```

Case 4) `N = 100`, `max_print = 10`, `per_line = 6`

```
0    1    2    3    4    5
6    7    8    9
90   91   92   93   94   95
96   97   98   99
```

There should be a line feed between the front part and the rear part. Observe the sample runs using sortx.exe provided with you.

Tips and Hints: If you observe the skeleton code provided, it has two functions as shown below:

```
void _printList(int *list, int start, int end, int per_line) {
    int count = 1;
    for (int i = start; i < end; i++, count++) {
        // your code here
    }
    cout << endl;
}

void printList(int *list, int N, int max_print, int per_line) {

    // your code here .

    _printList( list, 0, __, per_line ); // print the front part of list
    _printList( list, __, __, per_line ); // print the rear part of list
}
```

This code makes sense since the front part and rear part of printing must be the same. This is just an idea or example to avoid the duplicated code (DRY).

Building an executable with lib/libnowic.a and libsort.a

In this problem set, we are using user-defined functions stored in a static library called libnowic.a and libsort.a. The library **libnowic.a** has many functions such as GetChar(), GetInt() and GetString() that are used to get a specific data type of input from users, just to name a few. You may refer to ~/include/nowic.h for detail.

The command script to build an executable using the libsort.a and lib/libnowic.a (libnowic_mac.a for Mac) and include/nowic.h is shown below:

```
$ g++ sortDriver1.cpp -I../include -L../lib -lnowic -lsort -o sort
```

For Mac:

```
$ g++ sortDriver1.cpp -I../include -L../lib -lnowic_mac -lsort -o sort
```

NOTICE:

1. Uppercase I specifies an header folder
2. Uppercase L specifies a **lib** folder where the **library files** exist.
3. Lowercase l specifies the library file without lib in front. **-lnowic** indicates that its library name is **libnowic.a** and **-lsort** for **libsort.a**

Once you feel comfortable in building your executable using the command line, you write a makefile script as well to work with. There are quite different levels of build scripts you can write. Any form of build script will be accept at least it can build an executable with two static libraries and one source file.

Step 3: Using a function pointer:

Function Pointers provide some extremely interesting, efficient and elegant programming techniques. You can use them to replace switch/if-statements, to realize your **own late-binding** or to implement **callbacks**.

Unfortunately - probably due to their complicated syntax - they are treated quite carelessly in most computer books and documentations. If at all, they are addressed quite briefly and superficially. They are less error prone than normal pointers because you will never allocate or deallocate memory with them. All you've got to do is to understand what they are and to learn their syntax. But keep in mind: Always ask yourself if you really need a function pointer.

It's nice to realize one's own **late-binding** but to use the existing structures of C/C++ may make your code more readable and clearer.
(<http://www.newty.de/fpt/intro.html#why>)

You may watch this lecture (<https://dojang.io/mod/page/view.php?id=592>) about the function pointer in Korean.

Definition

Function Pointer is a pointer, i.e. a variable, which points to the address of a function. You must keep in mind, that a running program gets a certain space in the main-memory. Both, the executable compiled program code and the used variables, are put inside this memory. Thus, a function in the program code is, like e.g. a character field, nothing else than an address. It is only important how you, or better your compiler/processor, interpret the memory a pointer point to.

Instead of referring to data values, a function pointer points to executable code within memory. When dereferenced, a function pointer can be used to invoke the function it points to and pass its arguments just like a normal function call. [from Wikipedia]

Function pointers can be used to simplify code by providing a simple way to select a function to execute based on **run-time values**. It is so called late-binding.

A function pointer always points to a function with a specific signature! Thus all functions, you want to use with the same function pointer, must have the **same parameters and return-type!**

Simple Example

Suppose that we have a very simple function to print out the sum of two numbers and returns the sum. Let us see how we can create a function pointer from there.

```
#include <iostream>
```

```
using namespace std;

int fun(int x, int y) {                // function implementation
    return x * 2 + y;
}

int foo(int x, int y) {
    return x + y * 2;
}

int add(int x, int y) {
    return x + y;
}

void main() {                        // using function pointer
    int (*fp) (int, int) = fun;      // & is optional
    cout << "fp() returns " << fp(2, 3) << endl;
    fp = foo;
    cout << "fp() returns " << fp(2, 3) << endl;
}
```

Sample run:

```
fp() returns 7
fp() returns 8
```

Facts About Function pointers

Differences from normal pointers:

- A function pointer points to code, not data. Typically, a function pointer stores the start of executable code.
- We do not allocate nor de-allocate memory using function pointers.

Same as normal pointers;

- We can have an array of function pointers.

```
int main() {
    // fp is an array of function pointers
    int (*fp[])(int, int) = { fun, foo, add };
    for (int i = 0; i < 3; i++)
        cout << "fp(" << i << ") returns " << fp[i](2, 3) << endl;;
}
```

A function pointer can be passed as an argument and can also be returned from a function. This feature of the function pointer is **extremely useful**. In OOP, class methods are another example implemented using function pointers.

Make use of a function pointer

Using a function pointer, we would like to simplify our sort driver program a bit.

(1) Copy sortDriver1.cpp to **sortDriver2.cpp**

- (2) Declare a function pointer variable for many sort functions to begin with. For example:

```
void (*sortFn)(int *, int);           // sort function pointer
```

- (3) Set the function pointer with a default sort function. This code exists before the menu starts.
- (4) As a user selects a sort algorithm at the menu item 'a', update the function pointer with the sort function the user selects.
- (5) As a user selects the menu item 's' – sort(), invoke a sort function which is stored in the sort function pointer. This means that your code for cases of 'a' and 's' becomes simple – only several lines. For example,

```
start = clock();
sortFn(list, N);
end = clock();
```

Submitting your solution

- Include the following line at the top of your every source file with your name signed.
On my honor, I pledge that I have neither received nor provided improper assistance in the completion of this assignment.
Signed: _____ **Student Number:** _____
- Make sure your code **compiles** and **runs** right before you submit it. Every semester, we get dozens of submissions that don't even compile. Don't make "a tiny last-minute change" and assume your code still compiles. You will not get sympathy for code that "almost" works.
- If you only manage to work out the Project problem partially before the deadline, you still need to turn it in. However, don't turn it in if it does not compile and run.
- Place your source files in the folder you and I are sharing.
- After submitting, if you realize one of your programs is flawed, you may fix it and submit again as long as it is **before the deadline**. You will have to resubmit any related files together, even if you only change one. You may submit as often as you like. **Only the last version** you submit before the deadline will be graded.

Files to submit, Due and Grade points

Files to submit:

- libsort.a and make.s – 0.5 point
- sortDriver1.cpp and make.1 – 2.5 points
- sortDriver2.cpp – 1 point

Due: 11:55 pm
